Rocket Revolution

A Statistical Study of ISRO's Launch Activities (2005-2025)

Descriptive statistical analysis of annual launch frequency and launch-vehicle usage, based on the official ISRO Launch Missions records

Study period: 1 January 2005 - 31 December 2025 (21 years)
Records analysed: 82 launches (85 entries in the compiled dataset)
Primary data source: ISRO Launch Missions database, https://www.isro.gov.in/ISRO_EN/LaunchMissions.html
Tools: Python (pandas, NumPy, SciPy, Matplotlib)

Summary

ISRO's launch records for 2005-2025 contain **82 launches** of its own launch vehicles, an average of **3.90 per year** (median 3, SD 1.95, range 1-7). Annual launches rose from a mean of **2.6 per year in 2005-2014** to **5.1 per year in 2015-2025**, about 2.0 times as many (Mann-Whitney U = 16.5, p = 0.006). The fitted linear trend is +0.19 launches per year (95% CI 0.08 to 0.31). Growth was interrupted in 2020-2021, when only 2 launches were made in each year.

The **PSLV** is the workhorse, flying **55 of 82 launches (67.1%)**, followed by the GSLV Mk II (15, 18.3%), the LVM3 (9, 11.0%) and the SSLV (3, 3.7%). The mix has diversified: PSLV's share fell from 77% to 62% as LVM3 and SSLV entered service. 75 of 82 launches (91.5%) were successful.

1. Introduction and objectives

India's space programme has used a family of launch vehicles to place communication, navigation, Earth-observation and scientific payloads into space. Looking at these missions over time shows how launch activity has developed. This project applies basic statistical methods to ISRO's own public launch records, with the emphasis on data collection, organisation, visualisation and interpretation. It does not use machine learning, satellite imagery or predictive modelling.

The objectives are:

- to compile ISRO launch mission records for 2005-2025;
- to calculate the annual number of launches and examine changes over time;
- to compare how often the different launch vehicles were used;
- to present and interpret the main findings with tables and graphs.

2. Data and methodology

2.1 Data source and compilation

All data come from the Launch Missions table on ISRO's official website. The table lists every mission launched from Satish Dhawan Space Centre (SDSC SHAR), Sriharikota, with its launch date, launcher type, payload and remarks. The 85 entries dated between 1 January 2005 and 31 December 2025 (ISRO serial numbers 20 to 104) were transcribed into a structured dataset (Appendix A and the accompanying CSV file). ISRO's table also contains older entries (1979-2004) and entries dated 2026, which fall outside the study period and were excluded.

2.2 Variables

Variable	Definition
launch_date	Date of launch exactly as listed by ISRO (local date)
year, month	Derived from the launch date
mission, payload	Mission name as listed by ISRO; headline payload taken from the mission title
vehicle_family	PSLV, GSLV (Mk II), LVM3 (ex GSLV Mk III) or SSLV. ISRO renamed GSLV Mk III to LVM3; both names are merged into one family
isro_launcher_type	Configuration cell as listed by ISRO (e.g. PSLV-XL, PSLV-CA); left blank or generic by ISRO for some entries
category	Orbital launch / suborbital test (LVM3 CARE) / technology demonstration
outcome	Success or failure (see 2.3)

2.3 Definitions and decisions

- **What counts as a launch.** ISRO's table includes three entries with no launcher type: the Reusable Launch Vehicle technology demonstrator (RLV-TD HEX, 23 May 2016), the Scramjet Engine technology demonstrator (28 Aug 2016) and the Pad Abort Test of the crew escape system (5 Jul 2018). These are technology tests, not flights of a launch vehicle, so they are kept in the dataset but **excluded from launch counts**. The LVM3 CARE flight (18 Dec 2014) is a suborbital experimental flight of an LVM3 vehicle; it is **included** as a flight of that vehicle and flagged. The analysed population is therefore **82 launches** (81 orbital attempts plus CARE). Section 3.5 repeats the main results under the other two definitions.
- **Outcome.** Six launches carry an 'unsuccessful' or 'not accomplished' remark in ISRO's table and are classed as failures. The SSLV-D1 launch (7 August 2022) has no remark in the table, but ISRO publicly announced that it placed its satellites in a 356 x 76 km orbit instead of 356 km circular and that they were 'no longer usable'; it is therefore also classed as a failure (7 failures in total). A launch is called a success when its vehicle is not flagged as failed; later problems with a spacecraft are not captured.
- **Periods.** For comparison the 21 years are split into 2005-2014 (10 years) and 2015-2025 (11 years).

2.4 Statistical methods

Annual counts are summarised with the mean, median, standard deviation, quartiles and range, and shown with a 3-year centred moving average. Changes over time are examined by comparing the two periods (Mann-Whitney U test, chosen because annual counts are small integers and not normally distributed), by an ordinary least-squares line of launches on year (slope with 95% confidence interval) and by Kendall's rank correlation tau between year and count. Vehicle usage is described by counts and percentage shares and cross-tabulated with year and period. Success rates carry Wilson 95% confidence intervals. The days between consecutive launches are summarised as a measure of launch cadence. With only 21 annual observations, the tests should be read as supporting evidence, not as proof.

3. Results

3.1 Annual number of launches

Figure 1 shows launches per year. Activity began modestly, with a single launch in each of 2005 and 2006, reached 3 per year by 2007, held at 2-3 launches per year until 2013 and then stepped up to 5 in 2014 and 2015. The record of 7 launches was reached in **2016, 2018 and 2023**. After 6 launches in 2019 the count fell to 2 in 2020 and 2021 and recovered to 5 in 2022, 7 in 2023, and 5 in each of 2024 and 2025.

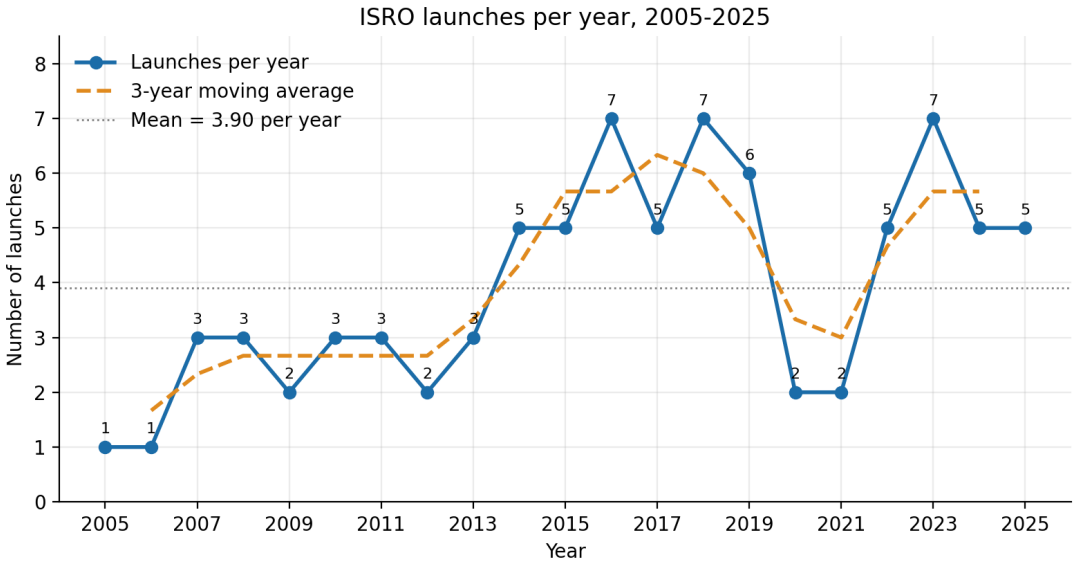

Figure 1. Number of ISRO launches per year, 2005-2025 (n = 82), with a 3-year centred moving average and the 21-year mean. The line chart requested in the project plan.

Table 1. Descriptive statistics of annual launch counts, 2005-2025.

Statistic	Value
Years observed	21
Total launches	82
Mean per year	3.90
Median per year	3
Standard deviation	1.95
Minimum (years)	1 (2005, 2006)
Maximum (years)	7 (2016, 2018, 2023)
Lower / upper quartile	2 / 5
Most frequent annual count	5 launches per year

Table 2. Launches per year by launch vehicle.

Year	PSLV	GSLV	LVM3	SSLV	Total	Year	PSLV	GSLV	LVM3	SSLV	Total
2005	1	0	0	0	1	2016	6	1	0	0	7
2006	0	1	0	0	1	2017	3	1	1	0	5
2007	2	1	0	0	3	2018	4	2	1	0	7
2008	3	0	0	0	3	2019	5	0	1	0	6
2009	2	0	0	0	2	2020	2	0	0	0	2
2010	1	2	0	0	3	2021	1	1	0	0	2
2011	3	0	0	0	3	2022	3	0	1	1	5
2012	2	0	0	0	2	2023	3	1	2	1	7
2013	3	0	0	0	3	2024	3	1	0	1	5
2014	3	1	1	0	5	2025	1	2	2	0	5
2015	4	1	0	0	5						

3.2 Changes over time

Between 2005-2014 ISRO made 26 launches (2.6 per year, SD 1.17); between 2015-2025 it made 56 (5.1 per year, SD 1.76). The later period's annual average is 1.96 times the earlier one, and the difference is statistically significant (Mann-Whitney U = 16.5, two-sided p = 0.006). A straight line through all 21 yearly counts rises by **0.19 launches per year** (95% CI 0.08 to 0.31, p = 0.003, R^2 = 0.39); Kendall's tau between year and count is 0.47 (p = 0.005), so the upward movement is consistent whichever method is used.

The 2020-2021 dip pulls the all-years slope down. Using only 2005-2019 the slope is steeper, 0.39 launches per year (R^2 = 0.79). This pre-2020 figure is a post-hoc comparison and is shown to illustrate the dip's effect, not as a separate hypothesis. The dip coincides with the COVID-19 pandemic, and 2021 also includes the failed GSLV-F10 launch, but annual launch counts alone cannot establish the cause. Since the recovery, launches have levelled off at about 5 a year (5, 7, 5, 5 in 2022-2025) rather than continuing the climb seen up to 2019, so a straight line is only a rough description of the whole period.

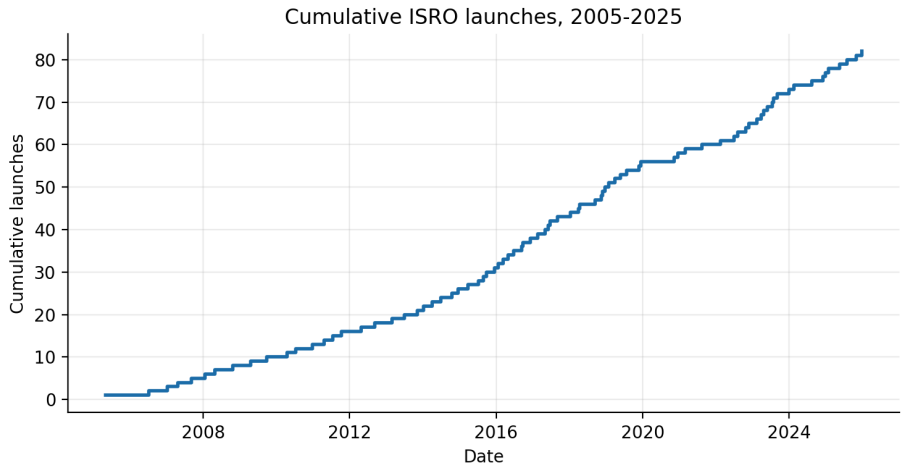

Figure 2. Cumulative number of ISRO launches. The slope steepens after about 2014 and flattens briefly in 2020-2021.

3.3 Launch-vehicle usage

Figure 3 compares how often each launch vehicle was used. The **PSLV** dominates with 55 launches (67.1%) and was flown in 20 of the 21 years (every year except 2006). The **GSLV Mk II** flew 15 times (18.3%), in 12 different years. The **LVM3** (GSLV Mk III) has 9 flights (11.0%), beginning with the CARE suborbital test in December 2014; it has been in every year since 2022 except 2024. The **SSLV** flew 3 times (3.7%) between August 2022 and August 2024.

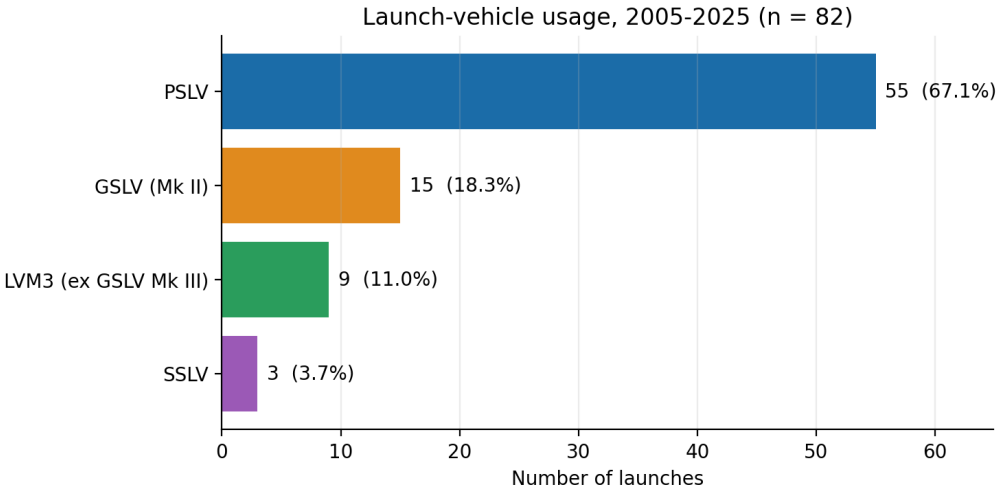

Figure 3. Launch-vehicle usage, 2005-2025: number and percentage of the 82 launches. The bar chart requested in the project plan.

Table 3. Vehicle usage summary.

Vehicle	Launches	Share (%)	First launch	Latest launch	Years used
PSLV	55	67.07	2005-05-05	2025-05-18	20
GSLV (Mk II)	15	18.29	2006-07-10	2025-07-30	12
LVM3 (ex GSLV Mk III)	9	10.98	2014-12-18	2025-12-24	7
SSLV	3	3.66	2022-08-07	2024-08-16	3

Table 4. Launches by vehicle in the two periods (counts, and launches per year).

Vehicle	2005-2014	2015-2025	2005-2014 per year	2015-2025 per year
PSLV	20	35	2.00	3.18
GSLV (Mk II)	5	10	0.50	0.91
LVM3 (ex GSLV Mk III)	1	8	0.10	0.73
SSLV	0	3	0.00	0.27
Total	26	56	2.60	5.09

The vehicle mix changed between periods. PSLV's share of launches fell from 77% (20 of 26) in 2005-2014 to 62% (35 of 56) in 2015-2025, even though PSLV launches per year went up (from 2.0 to 3.2). The increase in total activity therefore came from more PSLV flights *and* from new vehicles: LVM3 rose from 1 flight to 8, SSLV from none to 3, and GSLV Mk II from 5 to 10.

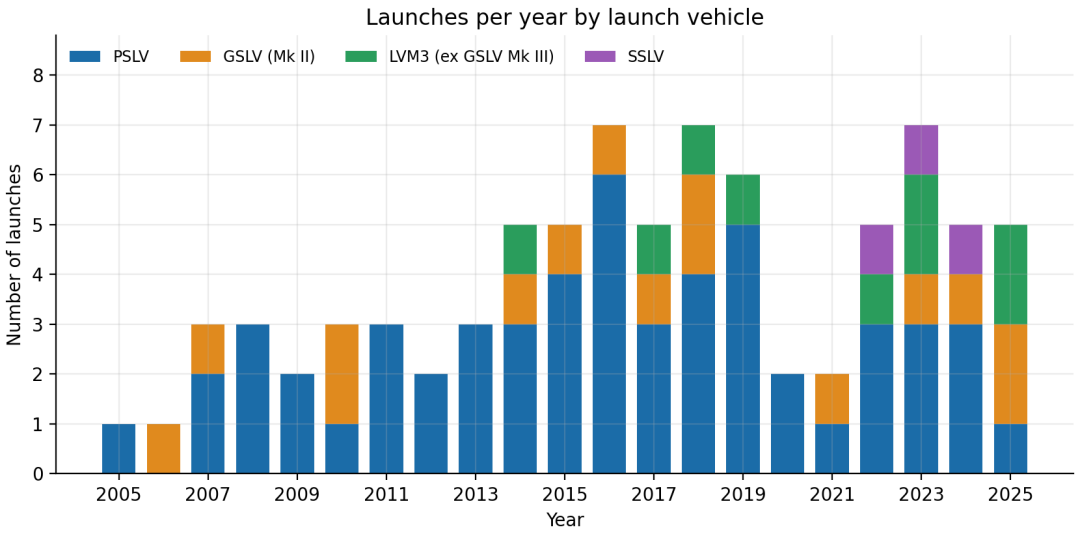

Figure 4. Launches per year, stacked by launch vehicle. PSLV is present almost every year; LVM3 and SSLV appear only in the later part of the period.

Within the PSLV family ISRO's table names several configurations. The most used was the six-strap-on PSLV-XL (25 launches), followed by PSLV-CA (14), PSLV-DL (4), PSLV-G (3) and PSLV-QL (2); for 7 PSLV launches the table gives only 'PSLV' or leaves the cell blank, so the configuration cannot be read from the source. For this reason the analysis works at vehicle-family level.

3.4 Launch outcomes and cadence

Of the 82 launches, 75 were successful (91.5%; 95% Wilson CI 83.4%-95.8%). PSLV succeeded in 53 of 55 launches (96.4%); its two failures were PSLV-C39 (2017) and PSLV-C61 (2025). GSLV Mk II had four failures in 15 launches (2006, two in 2010, 2021; 73.3% success), though its four launches in 2023-2025 all succeeded. LVM3 succeeded in all 9 flights, and SSLV in 2 of 3 (the failure being its first flight). With so few launches for LVM3 and SSLV, the confidence intervals are wide, so differences between vehicles' reliability should be read with caution.

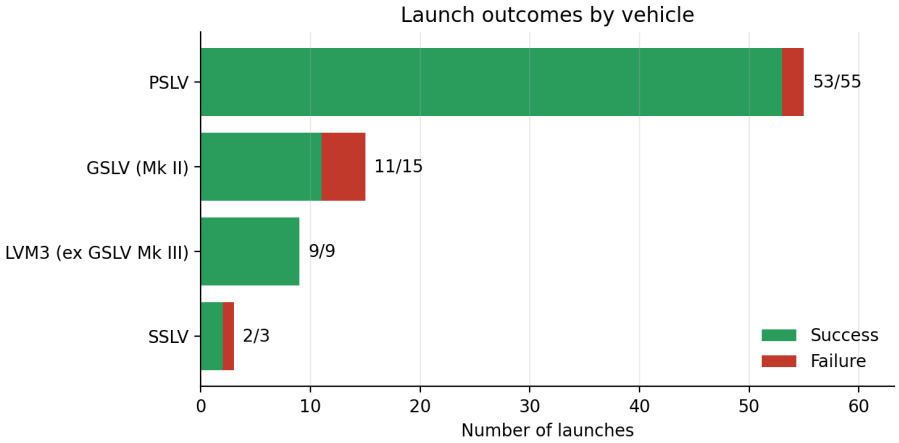

Figure 5. Launch outcomes by vehicle (successes in green, failures in red).

Table 5. Success rates by vehicle with Wilson 95% confidence intervals.

Vehicle	Launches	Failures	Successes	Success rate (%)	95% CI low	95% CI high
PSLV	55	2	53	96.36	87.68	99.00
GSLV (Mk II)	15	4	11	73.33	48.05	89.10
LVM3 (ex GSLV Mk III)	9	0	9	100.00	70.08	100.00
SSLV	3	1	2	66.67	20.77	93.85

Vehicle	Launches	Failures	Successes	Success rate (%)	95% CI low	95% CI high
All vehicles	82	7	75	91.46	83.41	95.80

Launch cadence. The time between consecutive launches averaged 93 days (median 77, SD 69), ranging from 14 to 431 days. The mean gap fell from 141 days (median 127) for launches in 2005-2014 to 72 days (median 57) in 2015-2025, which is the same change seen in the annual counts. The longest gaps were 431 days between PSLV-C6 (5 May 2005) and GSLV-F02 (10 July 2006) and 332 days between PSLV-C48 (11 Dec 2019) and PSLV-C49 (7 Nov 2020).

3.5 Sensitivity to the definition of a launch

Definition	Total	Mean/yr (all)	Mean/yr 2005-14	Mean/yr 2015-25	Slope per yr	Slope p-value
82 launches (main)	82	3.90	2.60	5.09	0.19	0.00
85 incl. 3 technology demonstrations	85	4.05	2.60	5.36	0.20	0.01
81 orbital attempts (CARE excluded)	81	3.86	2.50	5.09	0.20	0.00

Table 6. The main findings under three definitions of a launch. The conclusions do not depend on whether the three technology demonstrations are added or the CARE suborbital flight is removed.

4. Discussion

Launch activity has grown but not steadily. The clearest pattern is a step change around 2014-2015. In the first decade ISRO flew two to three times a year; since 2014 it has typically flown five or more. The two-period comparison, the regression slope and the rank correlation all point the same way, and the shorter intervals between launches show the same shift from a different angle. The pattern is not smooth, however: the 2020-2021 dip interrupted the climb, and the post-pandemic level of about five launches a year is below the peaks of 2016, 2018 and 2019 (6-7 launches each), although 2023 matched them.

The PSLV is the backbone, but the fleet is diversifying. Two-thirds of all launches used the PSLV, and it was flown in all but one year. Over the period the vehicle mix widened: the heavier GSLV Mk II and LVM3 (which carry larger satellites such as GSAT communications satellites, NISAR and the Chandrayaan missions) account for about three in ten launches, and the small-satellite SSLV was introduced in 2022. Within the data, the growth in launch counts came from both more PSLV flights and from new vehicles.

Reliability differs by vehicle, with limited evidence. The overall success rate is high (91.5%), with PSLV at 96.4%. The GSLV Mk II's four failures all occurred in 2006-2021, and the LVM3 has flown without a failure, but with 9 LVM3 and 3 SSLV launches the confidence intervals are wide, and a perfect record on few flights is not strong evidence of a lower failure rate.

What the statistics can and cannot say. These are descriptive results for one organisation over 21 years. They describe what happened; they do not explain why launches rose, dipped or recovered, and they should not be used to forecast future launch numbers.

5. Limitations

- **Launch counts are not capacity.** A launch is counted once whether it carried one satellite or several, and whether it was a small or heavy vehicle, so counts say little about payload mass or mission value.
- **Single source, manual transcription.** All records come from one ISRO web page, copied into a dataset by hand. The page may be updated or corrected later, and sounding rockets and other non-SHAR activities are not on it.
- **Classification choices.** Excluding three technology demonstrations, including the CARE flight, and classing SSLV-D1 as a failure are judgement calls (Section 2.3, Table 6).
- **Outcome means launch outcome only.** Partial failures or later spacecraft problems are not recorded. 'Success' means the launch was not flagged as a failure.
- **Small samples.** There are 21 annual observations, and 3 and 9 launches for two of the four vehicles. Tests assume independent years, which is only roughly true when activity shows trends, and the split at 2014/2015 is an analyst's choice.
- **Commercial and foreign payloads** (e.g. OneWeb, SPOT, TeLEOS) are counted as ISRO launches, because ISRO's table lists them.

6. Conclusion

ISRO's launch activity in 2005-2025 consists of 82 launches at an average of 3.9 per year. Annual launches roughly doubled between 2005-2014 and 2015-2025, with a pandemic-era dip in 2020-2021 and a plateau near five launches a year since 2022. The PSLV carried two-thirds of the programme, while the introduction of LVM3 and SSLV broadened the fleet. Simple descriptive statistics, a line chart of annual launches and a bar chart of vehicle usage are enough to show these patterns clearly and to demonstrate how basic statistical techniques can be applied to real space-science data.
